# Strategies to Improve CRT response

- Improve Patient Selection
- Device based optimisation

**Table 1. Summary of Echocardiographic Predictors of Response to CRT**

Echocardiographic Predictor	Description of Method	Echocardiography Method	Cutoff
SPWMD <sup>10</sup>	Septal-posterior wall motion delay; M mode measured by parasternal short-axis view	M mode	≥130 ms
IVMD <sup>14</sup>	Interventricular mechanical delay defined as the difference between left and right ventricular preejection intervals	Pulsed Doppler	≥40 ms
LVFT/RR <sup>14</sup>	Left ventricular filling time (LVFT) in relation to cardiac cycle length	Pulsed Doppler	≤40%

**Table 3. Interobserver and Intraoperator Variability Summary**

Echocardiographic Measure	Intraobserver CV, %	Interobserver CV, %	Interobserver $\kappa$ Coefficient*
LVESV	3.8	14.5	NA
LPEI	3.7	6.5	0.67
SPWMD	24.3	72.1	0.35
Ts-SD	11.4	33.7	0.15
Ts-peak (basal)	15.8	31.9	0.25

LPEI indicates left ventricular preejection interval.

segments at basal level

# Strategies to Improve CRT response

- Improve Patient Selection
- Device based optimisation

# Device based optimisation

- More recently focus has been shifting to device based optimisation
- Potential benefits over echo:
  - Simpler to perform
  - No inter-observer variability
  - Can optimise more frequently

# Device Companies

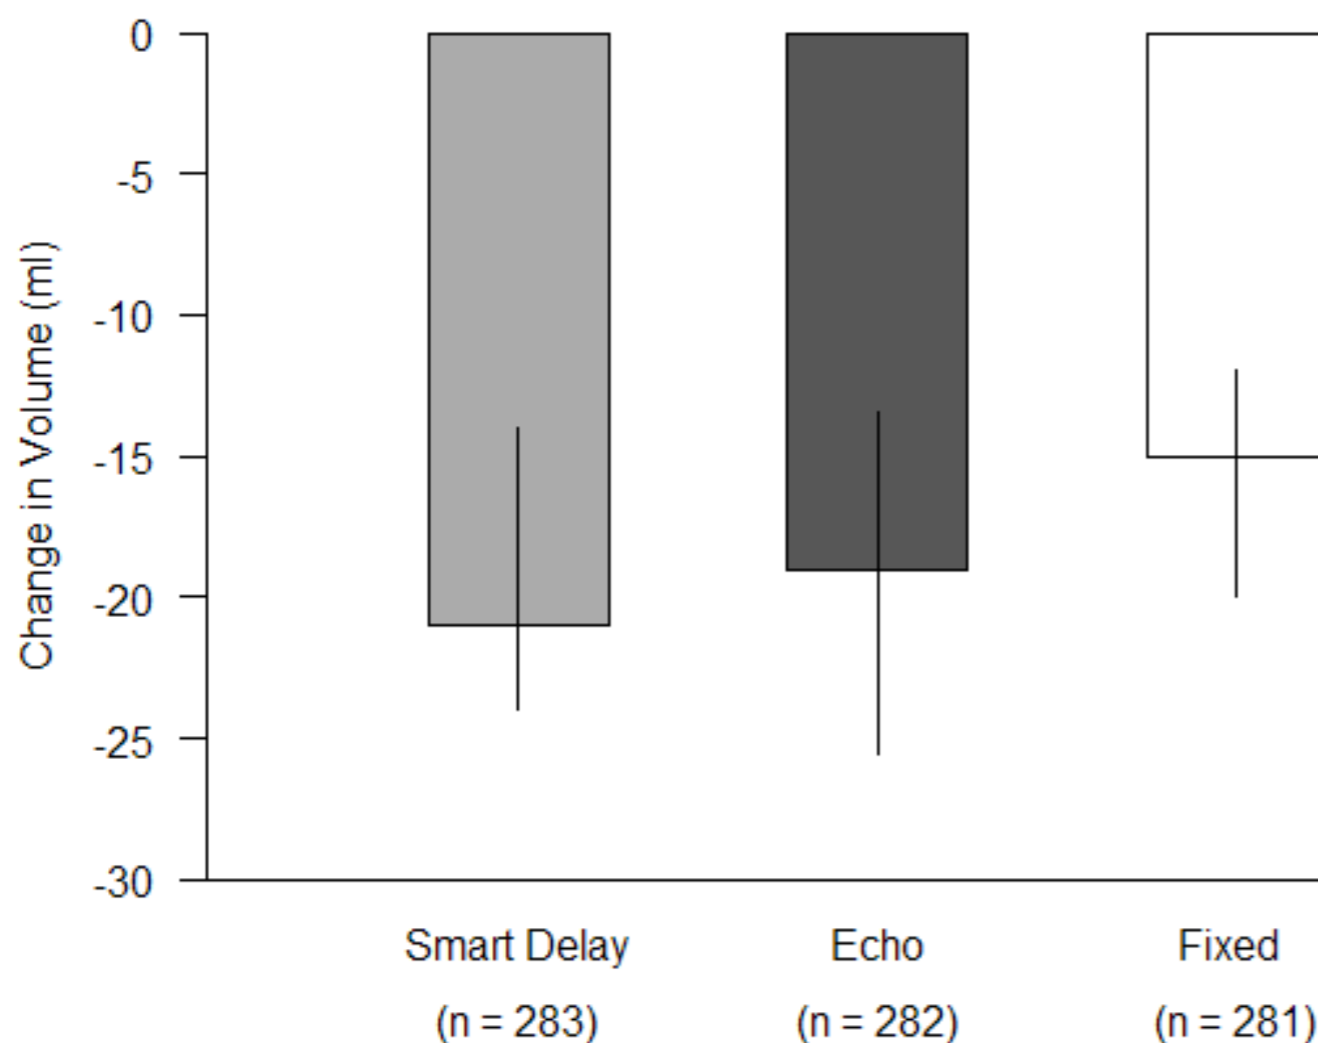

- Boston Scientific: Expert Ease for Heart Failure Smart Delay
- St Jude: Quick Opt, MPP
- Medtronic: Adaptive CRT, EffectivCRT, Multiple Point Pacing
- Sorin: SonR, Multiple Point Pacing

# Boston Scientific-Smart Delay

- Smart Delay provides both paced and sensed recommendations by accounting for three inputs:
  - Intrinsic AV intervals (Sensed AV and Paced AV intervals),
  - Interventricular timing (surface QRS duration)
  - LV lead location
- Algorithm was developed from the results of several previous acute clinical studies (PATH CHF, PATH CHF II, and SAVER)

# Boston Sci-Smart AV Trial

## Primary Endpoint - LVESV

## Primary Results From the SmartDelay Determined AV Optimization: A Comparison to Other AV Delay Methods Used in Cardiac Resynchronization Therapy (SMART-AV) Trial

### A Randomized Trial Comparing Empirical, Echocardiography-Guided, and Algorithmic Atrioventricular Delay Programming in Cardiac Resynchronization Therapy

Kenneth A. Ellenbogen, MD; Michael R. Gold, MD, PhD; Timothy E. Meyer, PhD; Ignacio Fernández Lozano, MD; Suneet Mittal, MD; Alan D. Waggoner, MHS; Bernd Lemke, MD; Jagmeet P. Singh, MD, PhD; Francis G. Spinale, MD, PhD; Jennifer E. Van Eyk, PhD; Jeffrey Whitehill, MD; Stanislav Weiner, MD; Maninder Bedi, MD; Joshua Rapkin, MS; Kenneth M. Stein, MD

**Background**—One variable that may influence cardiac resynchronization therapy response is the programmed atrioventricular (AV) delay. The SmartDelay Determined AV Optimization: A Comparison to Other AV Delay Methods Used in Cardiac Resynchronization Therapy (SMART-AV) Trial prospectively randomized patients to a fixed empirical AV delay (120 milliseconds), echocardiographically optimized AV delay, or AV delay optimized with SmartDelay, an electrogram-based algorithm.

**Methods and Results**—A total of 1014 patients (68% men; mean age,  $66 \pm 11$  years; mean left ventricular ejection fraction,  $25 \pm 7\%$ ) who met enrollment criteria received a cardiac resynchronization therapy defibrillator, and 980 patients were randomized in a 1:1:1 ratio. All patients were programmed (DDD-60 or DDDR-60) and evaluated after implantation and 3 and 6 months later. The primary end point was left ventricular end-systolic volume. Secondary end points included New York Heart Association class, quality-of-life score, 6-minute walk distance, left ventricular end-diastolic volume, and left ventricular ejection fraction. The medians (quartiles 1 and 3) for change in left ventricular end-systolic volume at 6 months for the SmartDelay, echocardiography, and fixed arms were  $-21$  mL ( $-45$  and  $6$  mL),  $-19$  mL ( $-45$  and  $6$  mL), and  $-15$  mL ( $-41$  and  $6$  mL), respectively. No difference in improvement in left ventricular end-systolic volume at 6 months was observed between the SmartDelay and echocardiography arms ( $P=0.52$ ) or the SmartDelay and fixed arms ( $P=0.66$ ). Secondary end points, including structural (left ventricular end-diastolic volume and left ventricular ejection fraction) and functional (6-minute walk, quality of life, and New York Heart Association classification) measures, were not significantly different between arms.

**Conclusions**—Neither SmartDelay nor echocardiography was superior to a fixed AV delay of 120 milliseconds. The routine use of AV optimization techniques assessed in this trial is not warranted. However, these data do not exclude possible utility in selected patients who do not respond to cardiac resynchronization therapy.

**Clinical Trial Registration**—URL: <http://www.clinicaltrials.gov>. Unique identifier: NCT00677014. (*Circulation*. 2010;122:2660-2668.)

**Key Words:** clinical trials, randomized ■ echocardiography ■ electrophysiology ■ heart failure ■ implantable cardioverter-defibrillators

**BACKGROUND** In patients with sinus rhythm and normal atrioventricular conduction, pacing only the left ventricle with appropriate atrioventricular delays can result in superior left ventricular and right ventricular function compared with standard biventricular (BiV) pacing.

**OBJECTIVE** To evaluate a novel adaptive cardiac resynchronization therapy (aCRT) algorithm for CRT pacing that provides automatic ambulatory selection between synchronized left ventricular or BiV pacing with dynamic optimization of atrioventricular and interventricular delays.

**METHODS** Patients (n = 522) indicated for a CRT-defibrillator were randomized to aCRT vs echo-optimized BiV pacing (Echo) in a 2:1 ratio and followed at 1-, 3-, and 6-month postrandomization.

**RESULTS** The study met all 3 noninferiority primary objectives: (1) the percentage of aCRT patients who improved in their clinical composite score at 6 months was at least as high in the aCRT arm as in the Echo arm (73.6% vs 72.5%, with a noninferiority margin of 12%;  $P = .0007$ ); (2) aCRT and echo-optimized settings resulted in similar cardiac performance, as demonstrated by a high concordance correlation coefficient between aortic velocity time integrals at aCRT and Echo settings at randomization (concor-

dance correlation coefficient = 0.93; 95% confidence interval 0.91–0.94) and at 6-month postrandomization (concordance correlation coefficient = 0.90; 95% confidence interval 0.87–0.92); and (3) aCRT did not result in inappropriate device settings. There were no significant differences between the arms with respect to heart failure events or ventricular arrhythmia episodes. Secondary end points showed similar benefit, and right-ventricular pacing was reduced by 44% in the aCRT arm.

**CONCLUSIONS** The aCRT algorithm is safe and at least as effective as BiV pacing with comprehensive echocardiographic optimization.

# Difference in responder rate for subgroups

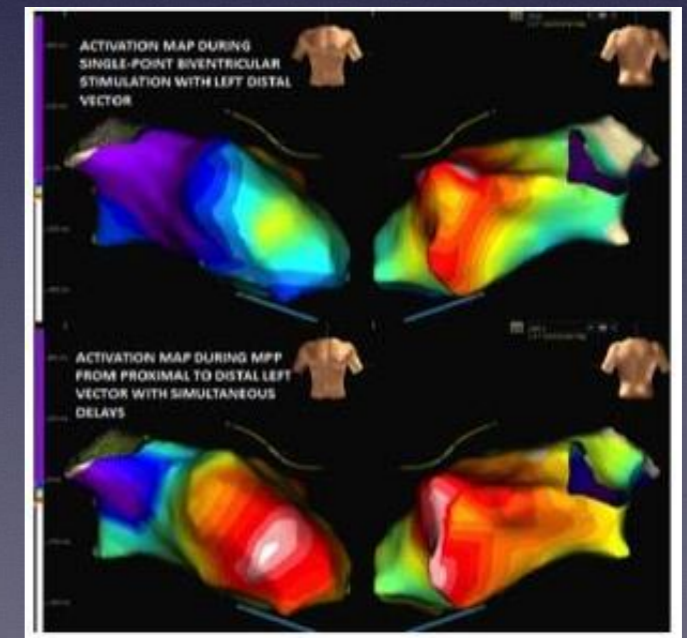

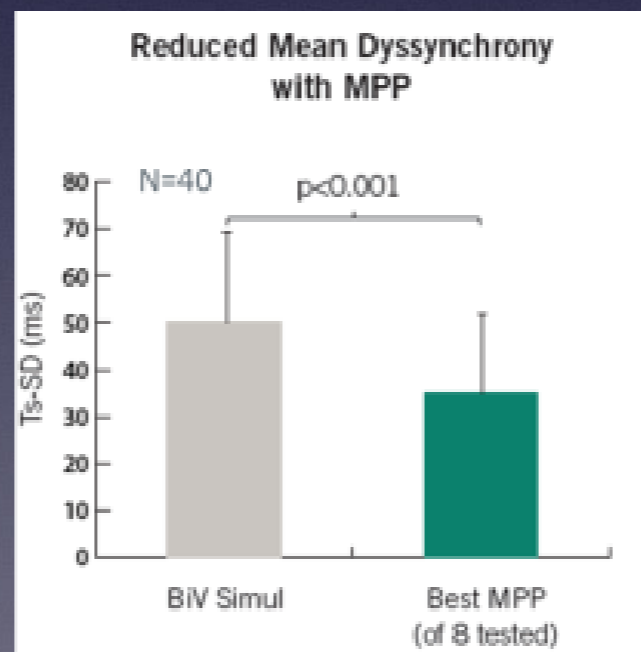

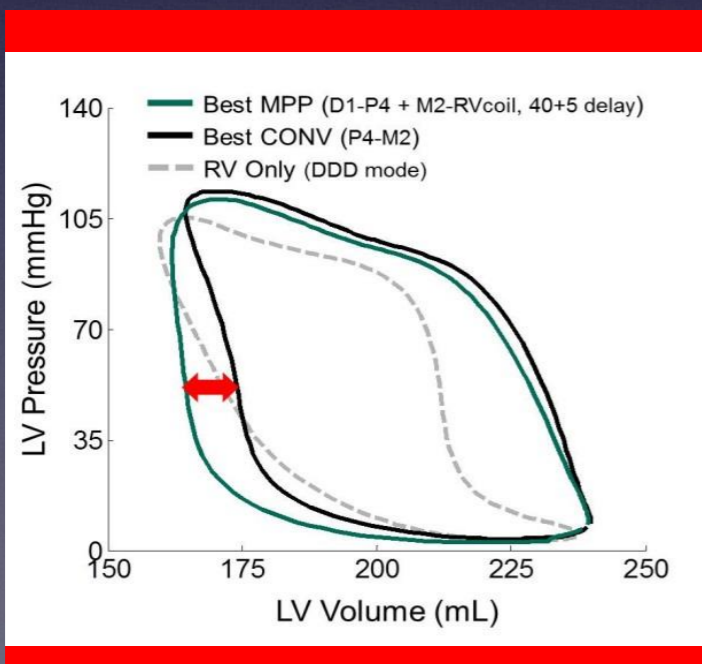

# Multi Point Pacing

- Pacing from **two** LV sites (“Multipoint LV stimulation”) and **one** RV
  - Capture a larger area
    - Engage areas around scar tissue
  - Improve pattern of depolarisation/repolarisation
  - Improve hemodynamics
  - Improve resynchronisation
- Using MPP does appear to reduce battery life by around 6-12 months

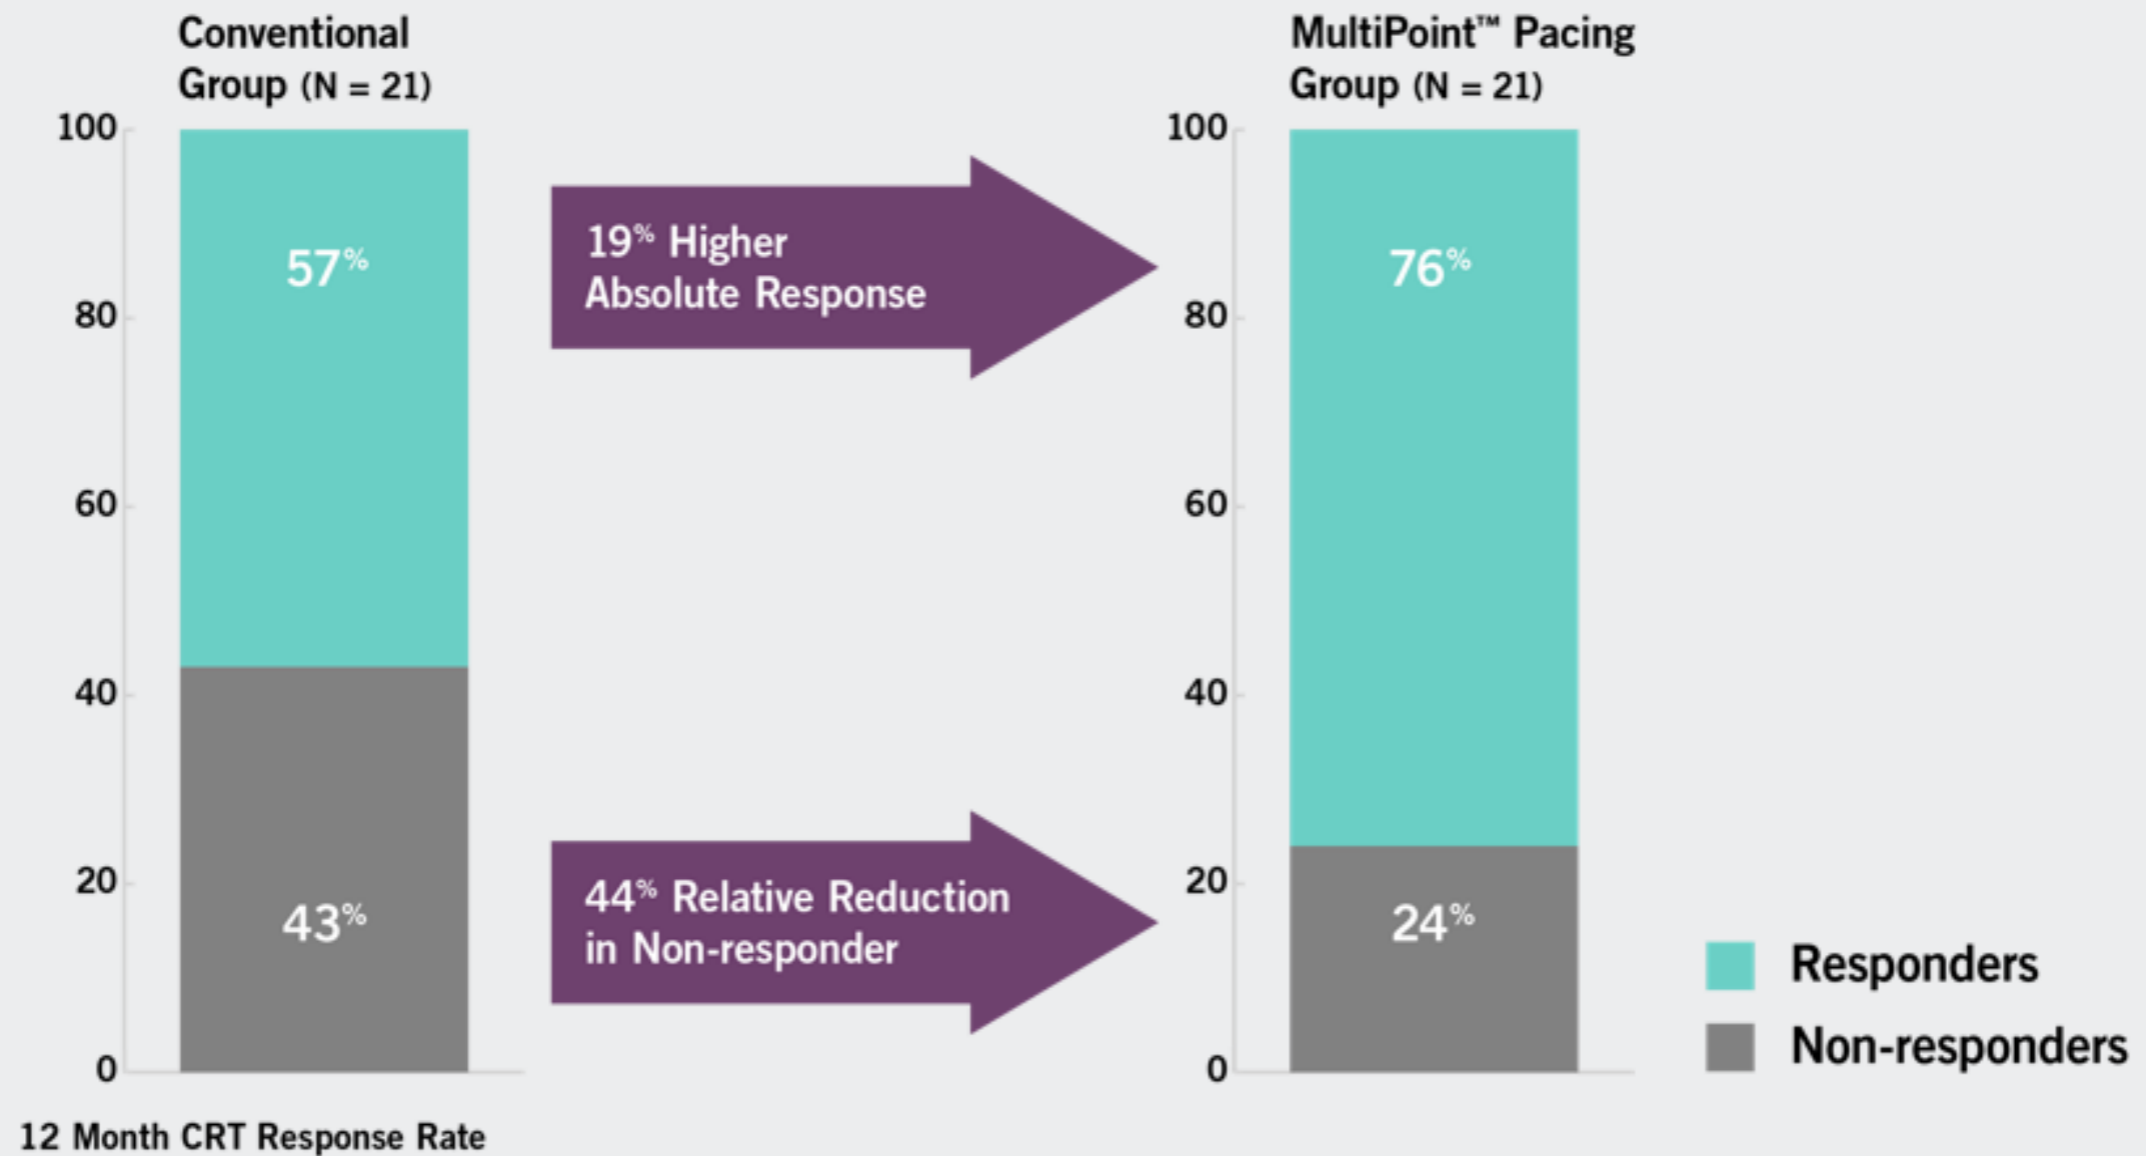

# Acute data for MPP

- Hemodynamic benefit:  
A study of 44 patients by Pappone et al. showed MultiPoint Pacing significantly improved acute LV hemodynamic parameters assessed with pressure-volume loop measurements.
- Mechanical benefit:  
Biventricular pacing with MultiPoint LV pacing reduced mechanical dyssynchrony measured with tissue Doppler in a multicenter study of 41 patients.
- Electrical benefit:  
MultiPoint pacing was able to recruit a greater portion of the LV than traditional biventricular pacing, resulting in reduced activation times and QRS duration.

# 12-MONTH CRT RESPONSE RATE<sup>7</sup>

Response definition:  
ESV reduction  $\geq 15\%$  and Alive Status

# MPP IDE Study

## **Safety and Efficacy of MultiPoint Pacing in Cardiac Resynchronization Therapy: The MultiPoint Pacing (MPP) IDE Trial**

Spatial Separation  
& > 5 ms Timing Delay  
(n = 32)

Spatial Separation  
& 5 ms Timing Delay  
(n = 52)

# Conclusions

- Echo based optimisation has very little evidence base for routine clinical work
- Device based algorithms are becoming more common and in initial trials do appear to confer some increased benefit
- Multi point LV pacing may also improve response but does have effect on battery life
- No head to head data across the different companies

Thank You..
